INTRODUCTION

The B-l aircraft, developed by the B-l Division of Rockwell International, utilizes an Electrical Multiplex System (EMUX) for:

- processing and transfer of serial-digital and discrete data throughout the aircraft
- power control of most electrical loads
- automatic electrical load management

There are two independent EMUX systems in the aircraft for redundancy - each having its own configuration and software. EMUX is programmed using an IBM 370 hosted compiler. Input to the compiler consists of logic equations, assembly language instructions, and EMUX system configuration data. EMUX can be programmed to output over two thousand signals as functions of over five thousand input signals. This magnitude of equations and signals complicates the understanding and analysis of the EMUX software.

In order to improve the Air Force EMUX software analysis capability, several in-house computer routines were developed from July 1975 to September 1977. All of these routines use copies of the same data files created and maintained by the B-l Division for use in generating the EMUX flight software. All of the routines were developed on Aeronautical Systems Division's CDC 6600 Computer System using FORTRAN EXTENDED.

One ASD Technical Report and four Avionics Directorate (ENA) Engineering Reports have been written to document the various computer programs:

- "B-1 EMUX Data Tape Conversion Software" ASD-ENA-77-20
- "B-1 EMUX Usage Analysis Software" ASD-ENA-78-2
- "B-1 EMUX Signal-Signal and Signal-Box Relationship Analysis Software" ASD-ENA-78-3
- "B-1 EMUX Logic Equation Regeneration Software" ASD-ENA-78-4
- "B-1 EMUX Automated Logic Diagrammer Demonstration Program" ASD-TR-78-17

This report discusses the FORTRAN software written for use on the CDC 6600 to demonstrate the feasibility of automatically creating logic diagrams of boolean equations directly from the contractor maintained computer data files. Diagrams, while being logically equivalent to equations, are pictorial representations of the equations and, as such, facilitate understanding. However, logic diagrams are quite time-consuming to draw manually; estimates upwards of two or more man-years for a single version of EMUX software have been given. Thus, a computerized diagramming technique which did not require special input data could provide cost and time savings if the automated diagrams were of equal quality (accuracy, readability, layout, etc.) as manual diagrams. Program BOLD (B-1 (One) Logic Diagrammer) is the result of this feasibility demonstration.

lantineacros on begained was becaused out to tis legantum really

PROGRAM DESIGN GROUNDRULES

Program BOLD was written in FORTRAN EXTENDED for use on Aeronautical Systems Division's CDC 6600 computer system using the following ground rules:

- the layout of the diagrams, expecially the positioning of the logic operator symbols, must be of equal or better quality when compared to manually drawn diagrams.
- any valid logic equation for EMUX must be diagrammable, including equations with time delays.
- the diagrams must accurately reflect the boolean equation logic.
- preparation of special input data must be minimized.
- program size, run time, and resultant cost must be less than manual costs.

All of these ground rules have been satisfied by BOLD as will be discussed in the following paragraphs.

The proper layout of the diagram is one of the most important measures of the success or failure of any computerized diagramming technique. Proper layout must consider the location of each of the logic operator symbols (gates) and the interconnection of the gates. A major portion of the logic in BOLD is involved in diagram layout. Listed below are the diagram layout rules which were established:

- flow of logic will be from left to right.
- no overlap of gates.
- gates will be arranged in columns (for readability and simplicity) and will be assigned to columns from right to left to minimize length of interconnect lines.
- interconnect lines will be straight whenever possible and will have at most two turns.
- no feedback or latch interconnect lines will be used but will be labeled as operator inputs (this is not inconsistent with EMUX operation but is probably not how the diagram would be done manually).
- crossover of interconnect lines will be minimized.
- time delays will be treated as two input operators. One input is the quantity to be delayed and the other input is the time delay duration.

Figures 1 and 2 are sample BOLD printouts of two different equation diagrams. As can be seen, the diagrams are "drawn" by the standard line printer rather than by a continuous line plotter (e.e., a CALCOMP plotter). This type of output was selected primarily because BOLD was intended to be a feasibility demonstration program rather than a final production-oriented program. As such, diagram output via line printer is simpler to obtain in terms of software logic complexity and program turnaround time. A logical modification to improve diagram readability to BOLD for production use would be the conversion to CALCOMP-type diagrams. While this would require the main program to be changed (approximately 25 to 30% rewrite), the methodology would be the same and no other subroutine changes should be required. At the same time, logic for feedback lines could be included if deemed desirable.

All equations diagrammed to date have accurately reflected the input equation logic. The only problems encountered but not solved were due to either improper input equation syntax or equation size in excess of BOLD capacities. Improper equation syntax (e.g., missing operator, missing parenthesis) would also cause problems for the contractor's EMUX compiler and can only be resolved by correcting the equation. Many data arrays are used in BOLD for storage of various types of equation information. The sizes of these arrays are related to each other to some extent but are somewhat arbitrarily established. There are no known theoretical limits to the equation size which can be processed; however, practical limits of computer memory available and desired turnaround time may prevent some "extreme" equations from being diagrammed. Present array sizes have rejected less than 1/2 of 1% of all equations input. Array size limitations would probably be improved by the conversion to CALCOMPtype diagrams. The present program is limited to a maximum of 8 pages of printout per equation which, when cut and taped together, will show the entire diagram. Limits on particular equation size parameters (e.g., number of parenthesis pairs, number of operators, number of operands per operator) are documented in the program listings.

BOLD uses the same data files maintained by the contractor for EMUX flight software programming. The only additional input required is the user's selection of the equation set to be diagrammed. The user has the flexibility to select individual equations or entire subsystems for diagramming.

While final conclusions on relative costs (automated diagrams versus manual diagrams) cannot be made until a production version of BOLD is created, a preliminary cost analysis resulted significantly in favor of automated diagrams.

PRINTOUT DESCRIPTION

While the BOLD printout, Figures 1 and 2, seems at first cryptic, it is understandable if examined in parts. The first line identifies the OCNEE signal designator (an aircraft standard signal identification scheme) for the equation diagrammed, the aircraft effectivity, and the section of EMUX (left or right) involved. (For Figure 1, the equation output signal designator is 2821-008 and the equation is used in the left section of EMUX on Aircraft 3.) The next three lines on the left identify the aircraft system, subsystem, and subsystem to which the signal is assigned. For Figure 1, sub-subsystem 2821 is the Internal Transfer portion of the Fuel Distribution System.) The line to the right of the system labels is an abbreviated signal description. (For Figure 1, the signal is a power control signal for the tank 1 transfer pump number 2821PP1.) The next set of lines is the actual boolean equation to be diagrammed as input to BOLD. Following the equation is a table of all signals that are used in the equation. Included with each signal designator is the signal description. The final part of the printout is the diagram. Due to line printer limitations, the diagram is not as readable as possible. Each logic operator (gate) is indicated with a box of asterisks with a letter inside. AND gates use the letter A, OR gates use the letter O, EXCLUSIVE OR gates use the letter X, Type 1 time delays use a dollar sign (\$), and Type 2 time delays use a question mark (?). Gates with more than two inputs have the left column of asterisks extended as necessary to accomodate all inputs. NOT'ed gate inputs are indicated with the letter 0 in place of an asterisk in the gate's leftmost column. Gate interconnecting lines use dashes, periods, and letter I's for their horizontal parts, corners, and vertical parts respectively. The readability of these line printer diagrams can be improved significantly merely by drawing over the connecting lines manually - as is done in Figure 2.

PROGRAM OPERATION

The process used by BOLD, as shown in Figure 3, starts with reading the next equation to be diagrammed into array EQN. In order to simplify processing throughout the rest of the program, the equation is converted into an internal coded integer format and is stored in array EQN1. Array VAR is loaded with signal names appearing in the equation. The integer code is shown below:

VALUES	REPRESENT
1 to 1000	index of signal name stored in VAR
1001 to 2000	value -1000 is the index of an operator in array OPR
2001	(left parenthesis
2002) right parenthesis
2003	* AND operator
2004	@ EXCLUSIVE OR operator
2005	+ OR operator
2006	= EQUAL operator
2007	' NOT operator
2010	\$ TYPE 1 TIME DELAY operator
2011	? TYPE 2 TIME DELAY operator
9999	replaced character
-2006	NOT EQUAL operator
-2000 to -1001	NOT'd operator, absolute value -1000 is the index of an operator in OPR
-1000 to -1	NOT'd operator input, absolute value is the index of a signal name stored in VAR

Due to parentheses and operator precedence, the equation cannot be simply scanned from left to right to determine the correct diagram.

Therefore, BOLD first scans EQN1 for parenthesis pairs and stores information on each pair in array PAR. Once the parentheses have been found, then the logic within each pair is sent to subroutine PARSE for analysis - the innermost pair being done first. As each pair is done, the logic and parentheses are replaced in EQN1 with the resultant output operator's index in OPR and with 9999's. After all parentheses have been removed, the entire equation is sent to PARSE for a final analysis.

PARSE semantically analyzes each portion of the equation, taking into account operator precedence, by scanning left to right five times (once for each operator type). The operator precedence used by PARSE is Type 1 Time Delays, Type 2 Time Delays, AND gates, EXCLUSIVE OR gates, and OR gates. During each of the five passes, the appropriate operator is tested for and, if found, is stored in array OPR along with its associated inputs. Thus, when PARSE is finished with the equation, all of the semantic equation information is stored in array OPR as shown below for operator i:

OPR (1, 1)	operator type code (2003, 2004, 2005, 2010, 2011)
OPR (1, 2)	number of inputs to this operator
OFR (1, 3)	x of x, y coordinates of location of operator on output page
OPR(1, 4)	y of x, y coordinates of location of operator on output page
OPR (1, 5) through OPR (1, 34)	operator input indices. Negative values indicate primed inputs. Absolute values from 1 to 1000 are signal name indices pointing to array VAR. Absolute values from 1001 to 2000 are inputs from other operator outputs. These values -1000 point to array OPR.

The present size of array OPR limits any one operator to 30 inputs maximum. It should be noted that OPR (i, 3) and OPR (i, 4), operator location information, are not defined by BOLD at this point in the equation processing.

The only remaining task before printing out the diagram is the determination of the location of each of the operators on the output page. This portion of the logic within BOLD was designed to:

- minimize crossover of interconnecting lines.
- minimize the number of operators which could not be connected due to the location of other operators

- maximize the use of straight line connections
- make all connections so that the logic flow is from left to right

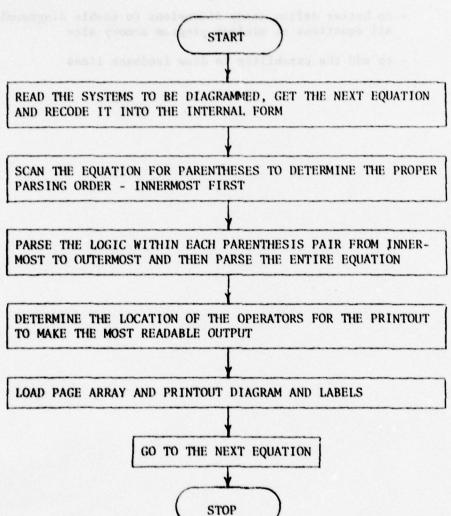

For both readability and ease of programming it was decided that each operator would be assigned to one of several available columns. Once an operator is assigned to a column then its vertical position in the column is determined based on providing the straightest connection from its output to the next operator's input. The operators are assigned to columns from right to left starting with the equation's overall output operator in the rightmost column. Its input operators are assigned to the next column to the left and their input operators are assigned likewise. This process is continued until all operators are assigned columns. Array OPOR is used to keep track of this process. When all operators are assigned columns, then OPR (1, 3) is defined for each operator.

OPR (1, 4) is defined by starting with the first, or top, operator in each column (right to left) and locating the operator if possible so that the connection from this operator to the one in the next column is straight. This is not always possible due to gate overlaps so the operator is moved down the column until no overlap occurs. As each column is finished, the next column to the left is done. This is continued until all columns are finished.

The final step in BOLD is to load the printout array PAGE with the operators, labels, and connection lines. This is a straight-forward process once the location of each operator is defined. In order to reduce computer memory requirements, 10 characters per word are packed into PAGE. Present dimensions of PAGE are 25,200. Up to eight pages can be used for diagram output with up to 200 lines per diagram and up to 250 characters per line.

BOLD DIAGRAM

CONCLUSION

Program BOLD has successfully demonstrated the feasibility of producing automated logic diagrams which are of equal quality to manual diagrams, which are less expensive than manual diagrams, and which can be obtained in much less time. Further development is required prior to production use of BOLD:

- to develop logic for utilization of plotter drawn diagrams
- to better define array dimensions to enable diagramming of all equations at minimum program memory size
- to add the capability to draw feedback lines

INPUT DE SCRIPTIONS

THE ONLY SET OF INFUT DATA CARDS IS IN LIST DIRECTED FORMAT AND IS USED TO SELECT THE SYSTEM, SUBSYSTEM, OR SUB-SUBSYSTEM TO BE DIAGRAMMED. THEY ARE SELECTED BY SURROUNDING THE FOUR DIGIT OCNEE NUMBERS WITH QUOTES, BY USING COMMAS AS SEPARATORS, AND BY PLACING A SLASH AT THE END. SINGLE EQUATIONS CAN ALSO BE SELECTED BY INPUTTING THE SIGNAL DESIGNATOR OF THE DESIRED EQUATIONS AS DESCRIBED ABOVE. UP TO 40 CAN BE SELECTED. AN ADDITIONAL FORTY-FIRST VALUE, IF INPUT AS NON-ZERO, WILL FORCE THE ERROR FRINTOUT FOR ALL DIAGRAMS.

OUTPUT DESCRIPTION:

ONE OR MORE PAGES ARE OUTPUT FOR EACH EQUATION. IN ADDITION TO THE LOGIC DIAGRAM, THE PRINTOUT HILL CONTAIN THE EQUATION AS READ FROM THE MASTER FILE, A TABLE OF SIGNAL DESCRIPTION INFORMATION FOR THE SIGNALS IN THE EQUATION, AND A HEADING HITH SYSTEM, SUBSYSTEM, AND SUB-SUBSYSTEM NAMES.

MAAC	DECCO	TOTT	-
NA 4 E	DESCR	THIT	UN

- ECHO DIAGNOSTIC PRINTOUT ROUTINE CALLED BY THE OPERATING SYSTEM WHEN FATAL EXECUTION ERRORS OCCUR.
- ERROR DIAGNOSTIC PRINTOUT ROUTINE CALLED WHEN SYNTAX ERRORS ARE FOUND AND WHEN LIMITS WOULD BE EXCEEDED. EQUATION INVOLVED IS SKIPPED. ARGUMENT 1 TELLS ERROR WHAT THE PROBLEM IS. A NON-STANDARD RETURN IS USED TO TERMINATE PROCESSING OF CURRENT EQUATION.
- GEIDAT ROUTINE TO GET RANDOM ACCESS DATA FROM TAPET. IF DATA CANNOT BE FOUND THEN QUESTION MARKS ARE PUT IN ARRAY DATA.
- INIT GENERAL INITIALIZATION SUBROUTINE. ARGUMENT 1 IS THE STARTING LOCATION, ARGUMENT 2 IS THE NUMBER OF LOCATIONS TO BE INITIALIZED. ARGUMENT 3 IS THE INITIALIZATION VALUE.
- THIS SUBROUTINE PROVIDES CHARACTER (LETTER OR NUMBER)
 OUTPUT FOR USE IN LABELING OPERATOR INPUT AND/OR OUTPUT
 LINES. ARGUMENT 1 IS A SIGNAL TO OUTPUT ALPHABETIC
 OR NUMERIC CHARACTERS. ARGUMENT 2 IS THE VALUE TO BE
 USED TO SELECT THE PROPER OUTPUT CHARACTERS. ARGUMENT 3
 IS THE OUTPUT TWO CHARACTERS LEFT JUSTIFIED WITH BLANK
 FILL. NON-STANDARD RETURN USED AS ABOVE.
- PACK
 THIS SUBROUTINE PACKS CHARACTERS INTO ARRAY PAGE
 (10 CHARACTERS PER WORD) FOR STORAGE OF THE DIAGRAM. AN
 ENTRY POINT (UNPACK) PROVIDES THE CAPABILITY TO GET
 CHARACTERS OUT OF PAGE. ARGUMENT 1 IS THE CHARACTER(S) TO
 BE STORED (PACK CALL) OR CHARACTER(S) TO BE RETRIEVED
 (UNPACK CALL). ARGUMENT 2 IS THE NUMBER OF CHARACTERS IN
 ARGUMENT 1. ARGUMENT 3 IS THE PRINTOUT COLUMN FOR THE
 FIRST CHARACTER. ARGUMENT 4 IS THE PRINTOUT ROW.
- PARSE THIS SUBROUTINE WILL PERFORM THE ACTUAL SEMANTIC PARSING OF EGN1(II) THROUGH EQN1(JJ). NON-STANDARD RETURN USED WHEN

ERROR OCCURS.

RELO4 SUBROUTINE TO SEARCH TAPE4 FOR THE NEXT EQUATION TO BE DIAGRAPHED. NON-STANDARD RETURN USED WHEN ERROR OCCURS OR FOR NORMAL JOB TERMINATION.

WRITTEN BY R.B. BERGER ASD/YHEJ 9 SEPT 75 FOR CDC 6600 FORTRAN EXTENDED VERSION 4.4.

         SET OPR(I,4) BY GOING THROUGH OPOR IN ORDER. PROCEDURE IS TO
C
         PLACE THE OPERATOR VERTICALLY SO THAT THE CONNECTION PATH IS
C
         STRAIGHT - IF POSSIBLE. OPERATORS ARE PLACED TOP TO BOTTOM
C
         WITHIN A GIVEN LEVEL - COL IS USED TO KEEP TRACK OF THE NEXT
C
         AVAILABLE POSITION IN EACH LEVEL SO THAT THE OPERATORS WILL
C
         HAVE AT LEAST TWO LINES BETWEEN THEM.
C
C
         SET OPE (NOPR, 4) AND THEN DO THE REST
C
     0 = R (NOPR, 4) = 0 FR (NOPR, 2) + MOD (OFR (NOPR, 2), 2) -1
      C) L (1) = OPR (NOPR, 4) + OPR (NOPR, 2) - MOD (OPR (NOPR, 2), 2) +3
C
         SET OPR(1,4) - NEED TO KNOW ITS INPUT POSITION. THE FIRST
C
    EXPRESSION IN THE MAXO IS THE HIGHEST AVAILABLE POSITION
C
C
         WITHOUT OWERLAP AND THE SECOND EXPRESSION IS THE DESIRED
C
         VERTICAL FOSITION FOR A STRAIGHT CONNECTION PATH

SJBROUTINE LABL(ALPNUM, VAL, CHAR), RETURNS(AAAAAA)

THIS SUBROUTINE WILL OUTPUT A THO CHARACTER LABEL. ALPNUM SIGNALS WHETHER AN ALPHABETIC (ALPNUM=1) OR A NUMERIC (ALPNUM=2) IS DESIRED. VAL IS THE INPUT VALUE TO BE USED TO GET THE LABEL. CHAR IS THE OUTPUT THO CHARACTERS - LEFT JUSTIFIED WITH BLANK FILL.

INTEGER ALPNUM, VAL, RCHAR, CHAR, R IF (AL PNUM.EQ.2) GO TO 10

MAKE AN ALPHABETIC LABEL
(A, B, C, D,..., Z,AA,AB,...,AZ,BA,BB,...,ZX,ZY,ZZ)
I'S AND O'S ARE NOT USED

MAKE A NUMERIC LABEL (01,02,03,...,10,11,12,...,97,98,99)

SJBRJUTINE PACK(AA, NAA, BB,CC), RETURNS(AAAAAA)

ROUTINE EITHER TO PACK CHARACTERS INTO ARRAY PAGE (10 CHARACTERS PER WORD) OR TO UNPACK CHARACTERS FROM ARRAY PAGE.

ARRAY PAGE IS USED TO STORE THE DIAGRAM PRIOR TO PRINTOUT. PAGE(1,J) WILL BE PRINTED ON THE JTH LINE STARTING AT COLUMN 10+(1-1)+1.

AA IS THE CHARACTER (S) TO BE PACKED INTO PAGE OR UNPACKED FROM PAGE - LEFT JUSTIFIED HITH BLANK FILL

NAA IS THE NUMBER OF CHARACTERS IN AA

88 IS THE PRINTOUT COLUMN WHERE AA IS TO BE PACKED INTO OR UNPACKED FROM

CC IS THE PRINTOUT LINE WHERE AA IS TO BE PACKED INTO OR UNPACKED FROM

ENTRY POINT PACK PUTS NAA CHARACTERS FROM AA INTO PAGE AT ROW CC AND COLU4NS BB THROUGH BB+NAA-1.

ENTRY POINT UNPACK GETS NAA CHARACTERS FOR AA FROM PAGE AT ROW GC AND COLU4NS BB THROUGH 88+NAA-1.
